## **Biogas: a powerful and safe enabler of decarbonisation & complementing the zero-pollution ambition of the Green Deal**

Biogas and biomethane producers have big expectations and are ready to play their role to deliver on the objectives of the Green Deal. By providing 14% of renewable energy available for final consumption (573,718<sup>1</sup> Terajoule out of 4,054,255<sup>2</sup> Terajoule), biogases are crucial to decarbonise the energy sector and the whole economy. Various independent reports and peer-reviewed studies<sup>3</sup> have shown the large contribution biogas can make in the needed decarbonization. However, the bioeconomy should not only provide renewable energy, but it should also offer the solutions for healthy and secure ecosystems for the people as well as all the animal and plant species.

The evidence that EBA collected from the biogas sector during its > 10 years of experience shows that proper biogas production based on sequential cropping is a sustainable activity. On top of that, it is a powerful agroecology solution leading to decreased greenhouse gas (GHG) emissions, protection of biodiversity and restoration of soil quality. Ultimately, if done correctly, sequential-cropping-based-biogas is a sustainable activity that promotes a carbon negative agriculture with increased organic fertilization leading to greater environmental protection.

It should also be noted that the diversified revenues from renewable energy facilitate to manage agricultural commodity markets. These new sources of income help to stabilise the prices of the agricultural commodities and they provide greater security for consumers and farmers. The rising potentials have already encouraged investments in farm, rural areas, and agricultural research that led to more sustainable yields<sup>4</sup>. This is beneficial for the overall production of the agricultural goods.

### **The main benefits of sequential cropping production**

When done correctly, sequential cropping generates several benefits for the economy, the natural capital and public health:

1. Biogas with sequential cropping is not only carbon neutral but it is carbon negative

Sequential cropping is aligned with food and feed production and it prevents indirect land-use change. The Consorzio Italiano Biogas (CIB) developed a pioneering approach which combines agroecology and anaerobic digestion<sup>5</sup>. Known as Biogasdoneright®, it brings major reduction of GHG emissions and increased CO<sub>2</sub>

Scarlat et al, *Biogas: Developments and perspectives in Europe*, Renewable Energy 129 (2018) 457-472, 2018; W. Terlouw et al, *The optimal role for gas in a net zero emissions energy system*, Navigant, 2019; D. Peters et al., *Assessing the case for sequential cropping to produce low ILUC risk biomethane*, Ecofys, 2016; L. Kemp, *Second Harvest: Bioenergy from Cover Crop Biomass*, Natural Resources Defense Council (NRDC), 2011.

<sup>4</sup> Improved techniques such as minimum tillage, precision agriculture and crop rotations, and new crop varieties have already been introduced and should be further supported to help the agriculture sector to transition towards decarbonization.

<sup>5</sup> Biogasdoneright® model was firstly introduced in Italy by Consorzio Italiano Biogas (CIB) as an agroecological transformation of the conventional production to sustainably supply biomethane. Additional crops are grown before or after the harvest of the main crop on the same agricultural land. More information available at <https://www.consorziobiogas.it/wp-content/uploads/2017/05/Biogasdoneright-No-VEC-Web.pdf>

sequestration in soil via the natural photosynthesis. Developing bioenergy with carbon capture and storage (BECCS) innovation will ensure even greater GHG savings and to produce carbon negative biogas.

## 2. Replacing the mineral fertilizers with the digestate reduces GHG emissions

Anaerobic digestion enables the producers of biogas to recover the organic materials and nutrients into the digestate. The agriculture sector has already identified several uses for digestate as a fertilizing product, soil improver and bio stimulant. When the mineral fertilizers<sup>6</sup> are replaced with an in-house organic digestate, major GHG emissions from the chemical industry are prevented. Public and private investors are already supporting research, development, and innovation in the promising field of nutrient recovery and reuse. For instance, Horizon 2020 promotes new pilot projects to identify novel valorisation pathways<sup>7</sup>. A focus group on nutrient recycling<sup>8</sup> was created to assess the agronomic and environmental value of the derived products.

## 3. Biogas reduces GHG emissions from livestock farming

The critique that expanding biogas production will lead to increasing the livestock population is inherently wrong. When based on sequential cropping, agricultural biogas production relies to a lesser extent on manure input from livestock. Also, farmers who use the organic digestate are less dependent on manure for fertilisation purposes. Furthermore, installing anaerobic digestion plants to produce biogas, allows methane emissions from handling livestock manure to be reduced. When the latter is brought to the closed and controlled environment of a biogas plant, methane is captured and transformed in renewable energy.

## 4. Restoring healthy soils, rich in humus and carbon content enables farmers to grow nutritious food and to remove CO<sub>2</sub> from the atmosphere

Farmers rely on healthy and fertile land to grow nutritious food. Soil content of humus and carbon are very important indicators to assess soil health and fertility. Soils which are rich in humus are also more resilient to climate change. Building humus in soil is possible when the land is covered with plants all year long. More plants on the field also increase the natural photosynthesis activity and the removal of the CO<sub>2</sub> from the atmosphere. When the farmers carry out minimum tillage and other agro-ecological techniques, the CO<sub>2</sub> that has been transferred to the land is stored for a long time.

## 5. Biodiversity conservation

EBA Members understand the need to protect the natural capital and are ready to apply the latest environmental standards and techniques that protect nature and biodiversity. When sequential cropping is done in a regime of crop rotation, also biodiversity is promoted. We are all prompt to work with the stakeholders and politicians to achieve the best outcome for the natural ecosystems.

Some of those benefits have been evaluated in €/MWh and are included in a report made by the prospective committee of the French regulator CRE. It says that for each MWh of biomethane produced, between 40 and 70€/MWh of positive externalities are generated.<sup>9</sup>

## **The current policy framework (and the proposed one) is biased**

Biogas producers must comply with the provisions laid down in the revised Renewable Energy Directive (EU) 2018/2001 (RED II) to claim that they generate renewable energy. The Directive includes strengthened sustainability criteria and it supports the shift towards advanced biofuels based on residues and non-reusable and non-recyclable waste, included in the Annex IX. At the same time, producers that produce renewable

<sup>6</sup> According to the fertilizing product regulation, fertilizers are divided into organic fertilizers and mineral fertilizers. Organo-mineral fertilizers are a blended version made of natural and chemical inputs.

<sup>9</sup> <https://atee.fr/system/files/2019-12/CRE%20Rapport-Gaz%202019.pdf>

energy from agricultural crops must certify their feedstock as climate friendly. The Commission Delegated Regulation (EU) 2019/807 supplements the Directive with criteria to certify low ILUC<sup>10</sup> risk biofuels, bioliquids and biomass fuels. Criteria are laid down in Art. 5, while Art. 6 regulates the auditing and verification requirements to get the low-ILUC certificate.

The current policy framework severely hinders biogas production as it fails to recognise that farmers can grow multiple crops on the same field – i.e. sequential cropping. In the past, mono crops of maize or other cereal were commonly grown and this often led to land use change. However, food and feed production are not displaced when the producers implement sequential cropping schemes. For instance, evidence shows that maize, triticale, wheat, or ryegrass silage can all be produced as additional (second) crop before or after the harvest of the main crop on the same agricultural land.

*We warmly recommend the Commission to recognise the low ILUC risk potential of such a practice which should be certified accordingly, as defined by the Delegated regulation (EU) 2019/807. If certified, this feedstock should also be included in the list of feedstocks for advanced biofuels laid down in Annex IX.*

We also note that the proposed regulation COM(2018) 392 to reform the European Agricultural Guarantee Fund (EAGF) and the European Agricultural Fund for Rural Development (EAFRD) reintroduces the principle of setting aside a portion of the agricultural area to non-productive features. This system, coupled with the provisions of RED II and ILUC criteria, would generate an inefficient framework: on one hand, set aside reduces the available land to grow food, and on the other hand ILUC criteria promotes harvesting food crops to the detriment of biogas.

We believe that such a framework is extremely burdensome and inefficient. It restricts freedom of producers to organize and operate. They are obliged to grow food and feed even when it will not pay off. Most likely, unsold goods will become waste although Member States should take measures to reduce food waste in line with the 2030 Agenda for Sustainable Development. Finally, operators become even more reliant on CAP expenditures to sustain their activities.

We warmly recommend the European Commission (EC) to recognise that sequential cropping is not only a powerful resource to produce biogas. It also allows farmers to restore and enhance soil quality, while they provide safe space for biodiversity. 4 out of 11 good agro-environmental conditions laid down in Annex III of the proposed regulation COM(2018) 392 promote soil maintenance and protection<sup>11</sup>. EBA is in favour of an even more ambitious CAP to protect and restore soil quality. EBA proposes to establish a European target for 2030 to restore carbon content in soils and a European target for 2030 to restore soil organic matter.

## Renewable Energy potential of biogas

In 2018, indigenous production of biogas from EU 27 amounted to 14% of the overall renewable energy available for final consumption (580,325 Terajoule<sup>12</sup>, out of 4,054,255 Terajoule<sup>13</sup>).

Biomethane is a renewable fuel produced via biogas upgrading or biomass gasification. Biomethane can directly replace natural gas in all its existing applications with minor investments. The great advantage of replacing natural gas with biogas is that no major infrastructure adjustment is needed. **EBA members are ready to work with the EC and all relevant stakeholders to decarbonise the gas supply by 2050.**

<sup>13</sup> [nrg\_bal\_s] – availability of renewables and biofuels available for final consumption in EU 27 in 2018.

Recent estimates found that anaerobic digestion could deliver up to 62 billion m<sup>3</sup> of biomethane by 2050 (Figure 1). We believe that addition 892,800 (+53%) Terajoule of biomethane could be generated once Member States will implement also separate collection of bio-waste<sup>14</sup>.

## Recommendations: a coherent policy framework should enable climate targets to be met & environmental management and protection.

EBA acknowledges the need to protect human health, the environment, and the related ecosystem services, while providing renewable energy to decarbonise the economy. However, we consider that the effects of the current (or proposed) legislation restrict the producers' freedom to organize and operate, lead to generation of food waste, hinder farmers' competitiveness, and undermine the real potentials of biogas.

A coherent and supportive policy framework should recognise the benefits of biogas and the capacity to deliver on the objectives of the Green Deal. We warmly invite the **EC and all the stakeholders to work together to find the way to align biogas from agriculture with the Green Deal**. Biogasdoneright<sup>®15</sup> model could be used as a benchmark to set up minimum requirements to integrate safely and sustainably biogas with production of food and feed.

EBA and all its members are ready to engage in the challenge to drastically reduce GHG emissions by 2050. We are willing to offer our experience and to take part in a constructive dialogue over the long term. Our final goal is to be part of a cleaner system where safe recycled products offset the sourcing of finite materials. Where organic fertilization and agro-ecology replace harmful practices. Where the society does no longer put itself at the risk of climate change and pollution. And where the natural capital is protected.

### EBA proposes to

- Revise Delegated regulation (EU) 2019/807 so that sequential cropping can be certified for the production of low ILUC risk biofuels.
- Revise Annex IX of RED II to include secondary crops, grow under sequential cropping conditions, in the list of feedstocks for the production of advanced biofuels.
- Revise GAEC 2 and GAEC 3 of Annex III of the Proposal for a Regulation reforming Common Agricultural Policy to set a European target for 2030 to restore carbon and soil organic matter in agricultural soil.

<sup>14</sup> Bio-waste is the organic fraction of municipal solid waste after separate collection, defined in article 1, point (3), letter (b) of Directive (EU) 2018/851.
